

GENERAL DESCRIPTION

The 74LV1T08 is a single 2-input translating AND gate that is designed for 1.6V to 5.5V V_{CC} operation. The input features a low threshold circuit. When the supply voltage is at 3.3V, the input can match 1.8V input logic, allowing a level-up translation from 1.8V to 3.3V. Furthermore, the input pins can tolerate up to 5V and support level-down translation. For instance, when the supply voltage is at 2.5V, the output voltage can translate from 3.3V to 2.5V. With a reference to the supply voltage, the CMOS level of output can be at 1.8V, 2.5V, 3.3V and 5.0V. The wide supply voltage range makes the connection between generation of output levels and controllers / processors available.

OVERSTRESS CAUTION

1. Stresses beyond those listed in Absolute Maximum Ratings may cause permanent damage to the device. Exposure to absolute maximum rating conditions for extended periods may affect reliability. Functional operation of the device at any conditions beyond those indicated in the Recommended Operating Conditions section is not implied.
2. The input and output voltage ratings may be exceeded if the input and output clamp current ratings are observed.
3. It can reach up to 7V (MAX).
4. The performance capability of a high-performance integrated circuit in conjunction with its thermal environment can create junction temperatures which are detrimental to reliability.

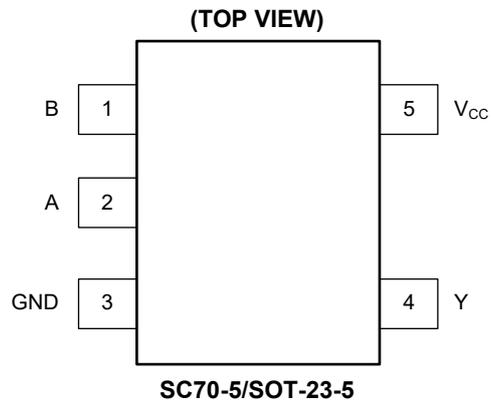

ESD SENSITIVITY CAUTION

This integrated circuit can be damaged if ESD protections are not considered carefully. SGMICRO recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage. ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because even small parametric changes could cause the device not to meet the published specifications.

NOTES:

- Specified by design and characterization; not production tested.
- t_{PD} is the same as t_{PLH} and t_{PHL}.
- C_{PD} is used to determine the dynamic power dissipation (P_D in μW).

$$P_D = C_{PD} \times V_{CC}^2 \times f_i \times N + \Sigma(C_L \times V_{CC}^2 \times f_o)$$
 where:
 f_i = Input frequency in MHz.
 f_o = Output frequency in MHz.
 C_L = Output load capacitance in pF.
 V_{CC} = Supply voltage in Volts.
 N = Number of inputs switching.
 Σ(C_L × V_{CC}² × f_o) = Sum of the outputs.
